 The only neuroimaging biomarker the FDA has approved has been the theta-beta ratio measured at the Cz electrode for diagnosis of ADHD in children (in 2013). However, this measure did not qualify as a standard biomarker but rather was to be used only in combination with clinical evaluation.

 Like blood and CSF, neuroimaging biomarkers assess alterations in inflammation and neuronal integrity as markers of neurotoxicity. Instead of measuring astrocytic activation via GFAP, imaging markers, such as translocator protein (TSPO), identify activation of microglia, the resident immune cells in the brain. 7,8.

On the Mark: Translating Biomarker Technology to Clinical Practice
 Neuroimaging studies have revealed structural and functional alterations in several neurological and psychiatric disorders, yet the impact of these findings on clinical practice has been very limited and at the present time there are no objective, biological, markers which can be used to make early diagnosis, prognosis and prediction of clinical outcome in these disorders.

 Late-onset Niemann-Pick type C (NP-C) is a rare, underdiagnosed lysosomal disease with neurological manifestations. A specific treatment, miglustat, can stabilize the disease if given early. Recently, three plasma screening biomarkers (PSBs) were developed [cholestane3β,5α,6β-triol (C-triol), 7-ketoc ...

 There already are molecular tests for diagnosing some neuropsychiatric disorders. Such neuropsychiatric disorders have a greater neurological than a psychiatric component. They include RTT (Eyal et al., 2019), HD (Nance, 2017), and FXS (Wattendorf and Muenke, 2005). It must be noted that the molecular tests for these disorders involve genetic rather than epigenetic testing.
