The selection, and design to a large degree, determine the amount of liquid carryover remaining in the gas phase. The most common types include wire mesh pads (mesh pads), vane-type (vane packs) and axial flow demisting cyclones. Figure 4 shows the location and function of a typical mist extractor in a vertical separator.

Unlike a water/oil separator which has a horizontal tank, a vertical tank is the best configuration for liquid/ gas separator. A vertical separator has smaller footprint than horizontal form, which makes it easier to install. Also, sand can be removed easier in vertical tank.

As the separator diameter increases to handle more liquid, the gas-handling capacity of the separator becomes increasingly underutilized, indicated by the declining value of K_s in Fig. 6. Even with the increasing liquid content over the range shown, the liquid levels are still set by the minimum distance constraints for the liquid level alarm and shutdown points.

Selection of separator: Horizontal or Vertical. As a rule, a vertical drum should be chosen when the ratio of vapor to liquid volume is large (750 or more). The vertical drum is often preferred since the separation efficiency does not vary with the liquid level in the drum. Also, the plot space required is lower for the vertical drum.

The selection of the orientation of a gas-liquid separator depends on several factors. Both vertical and horizontal vessels have their advantages. Depending on the application one has to decide on the best choice between the alternatives. Advantages of a vertical vessel are:

The goal for ideal separator selection and design is to separate the well stream into liquid-free gas and gas-free liquid. Ideally, the gas and liquids reach a state of equilibrium at the existing conditions of pressure and temperature within the vessel.
